

ABSTRACT OF THE DISCLOSURE

A nonreciprocal circuit device including a metal case through which a high frequency current is difficult to flow, and a communication apparatus incorporating the nonreciprocal circuit device. The cross section of the metal case has a rectangular-frame shape formed by inwardly bending a substantially rectangular metal plate at four positions at angles of 90 degrees in parallel to the short edges of the metal plate. The top ends of two arms of the metal case are opposed to each other at a specified distance. As a result, the metal case does not form a loop around a permanent magnet and a central electrode assembly.
